HISTORY OF LONG-LIFE CABLES

Nexans has an impressive long history as pioneers for designing and manufacturing quality medium voltage cables in New Zealand. As the largest power cable manufacturer in NZ and the only manufacturer of MV, we pride ourselves on delivering cable that has a life expectancy of over 50 years from our state of the art facility in New Plymouth, and have been since 1967.

In 1967, CANZAC cables were the first to manufacture the first-generation cross-linked polyethylene cables in the Southern Hemisphere and again were the first to introduce extruded semi-conductive screens to replace the taped version in 1973. In 1990, Olex Cables upgraded from steam to dry-cured triple extrusion and introduced the first-generation fire-retardant cross-linked polyethylene (TR-XLPE) in New Zealand. Eight years later, an X-ray 8000 dimensional controller was installed to the machine which scans through three layers of polymer to accurately measure layer thicknesses for consistency. After an improvement on the compound which was trialled in 1998, Olex Cables then went into full production of the second-generation TR-XLPE in 2005, reducing fire-growth even further. A new advanced hi-tech X-ray is installed the same year. Nexans Olex trialled the next generation of TR-XLPE in 2011 and went into full production in 2017, making Nexans NZ leaders in long-life cable.

Don't take a chance on the unknown

Have you ever considered why some cable products are so much cheaper than others? With cable, most of the cost is in the materials. If the price looks too good to be true, it almost certainly is!

Nexans have collaborated with our compound supplier for over 50 years to provide the best TR-XLPE material available on the market today, and our testing requires special equipment to ensure AS/NZS standards are not only met but exceed.

Investing in our cable gives you the very best of design, materials, refined manufacturing processes and quality test systems.

CONSTRUCTING LONG-LIFE CABLE

Nexans Medium Voltage TR-XLPE cables are designed in accordance with AS/NZS 1429.1:2006 and specific customer requirements where applicable to provide optimum performance for the end application.

The AS/NZS 1429.1:2006 is compatible with, and in some instances, exceeds, the requirements of the international standard IEC 60502.2. AS/NZS 1429.1 is also compatible with (UK) BS 6622 and (US) AEIC CS8 and ICEA S-93-639/NEMA WC74.

A – We use the highest grades of copper/aluminium and the latest technology in stranding to manufacture over 2 million metres of compacted MV cores a year.

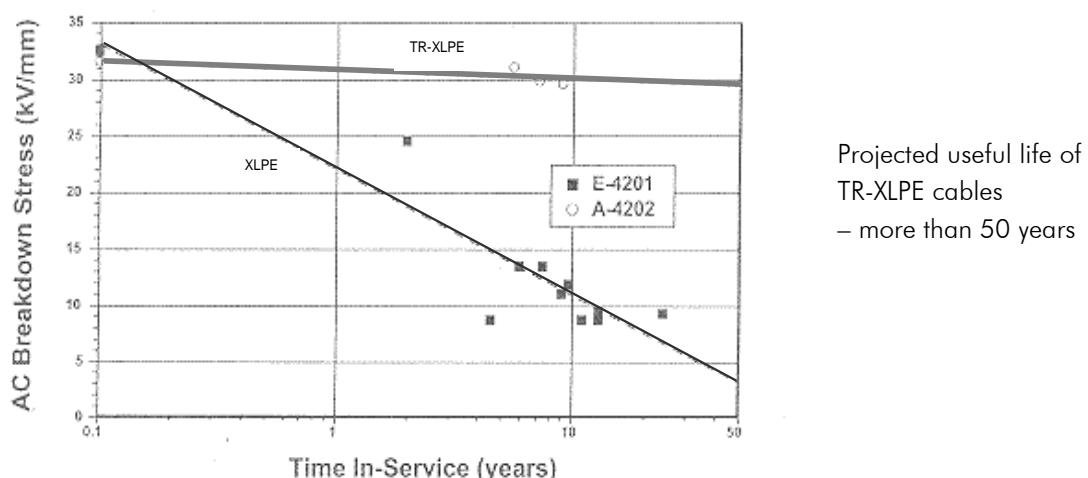

B – Utilising our state of the art machinery, our triple head extrusion process is fed raw materials from a pressurised clean room to ensure the interfaces between the materials are free of voids and contamination. The extruded core is then x-rayed to monitor wall thickness and concentricity.

C – A carefully controlled screening and cabling process using our expertise ensures the cable is manufactured to the highest standards, meeting our individual customers fault rating requirements.

D – Our sheathing is applied on our extrusion line using digitally controlled micrometres for highly accurate sheathing layers. Common sheathing materials are PVC, LLDPE, MDPE and HDPE.

Alternate designs incorporating aluminium foil laminate, steel wire armour or submarine cables can be produced upon request.

Once the construction of cable is complete, one of the most important test for medium voltage cable before it leaves our plant is the partial discharge (PD) test. This is carried out using special equipment and ensures that our MV cables are free of voids within the insulation, guaranteeing a life expectancy of over 50 years. Imported products may not meet the same quality due to testing carried out using only the equipment they have.

SCREEN DESIGNS

The standard range of Nexans Medium Voltage TR-XLPE cables rated up to and including 33 kV incorporates copper wire screens based on fault levels of either 3 kA or 10 kA for 1 second. If either of the standard screen designs does not suit a particular installation, the screen constructions can be tailored in size to meet the specific fault requirements of any operating system.

Wire Screen Cross Sectional Areas

In the case of three core cables which have screens around each individual core, the total screen cross sectional area is spread evenly over the three cores.

There are several other factors which can override the above criteria. Firstly, the screens are designed so that the average gap between the wires does not exceed 4 mm. This results in the screen area being increased above that required for the required fault level in certain cases. Secondly, the screen area is limited to a value so that its fault rating does not exceed that of the conductor. In some cases, the smaller cables in a range have fault levels of less than either 3 kA or 10 kA for 1 second respectively.

Screen Short Circuit Ratings

The screen short circuit ratings are calculated in accordance with formulae given in IEC 60949. Based on AS/NZS 1429.1 a starting temperature of 80°C and a final temperature of 250°C are used. The formulae are based on adiabatic conditions ie, no dissipation of heat during the short circuit.

The fault rating **I_{sc}** of a copper wire screen of a given cross sectional area can be calculated for any duration from the formula:

$$I_{sc} = \frac{148.6 * S}{\sqrt{t}} \text{ (A)}$$

Where: S = Screen Area (mm²) and t = Fault Duration (s).

Conversely, the screen area required for a given fault rating can be calculated as follows:

$$S = \frac{I_{sc} * \sqrt{t}}{148.6} \text{ (mm}^2\text{)}$$

For convenience, fault ratings for durations of 1 second are often quoted and this simplifies calculations since $\sqrt{t} = 1$ and this term disappears from the formulae.

TESTING

Testing of Nexans Medium Voltage TR-XLPE cables is carried out in accordance with AS/NZS 1429.1:2006.

The tests performed are:

Routine tests* - "tests made by the manufacturer on all completed cable to demonstrate the integrity of the cable."

Sample tests* - "tests made by the manufacturer on samples of completed cable, or components taken from a completed cable, at a specified frequency so as to verify that the finished product meets the design specification."

Type tests# - "tests made by a manufacturer before supplying commercially a type of cable in order to demonstrate satisfactory performance characteristics to meet the intended application. These tests are of such a nature that, after they have been made, they need not be repeated unless changes are made in the cable materials, design, or method of manufacture, which might change the performance characteristics."

* All routine and sample tests are performed in the factory.

Type tests are carried out within the Nexans group, which includes a separate laboratory dedicated to EHV cable testing. The extensive facilities include high voltage test equipment which can perform partial discharge measurements at voltages up to 300 kV, high voltage break-down tests to 600 kV, cyclic ageing tests and impulse withstand tests. This allows all type tests to AS/NZS and other national standards to be performed.

Tests Performed on Cables

| Routine Tests | Sample Tests | Type Tests |
|---|--|---|
| Spark test on sheath. | Thicknesses of extruded components. | Insulation resistance at 20°C and 90°C. |
| Conductor examination and resistance. | Screen and armour wire diameters, and screen area. | Elongation at rupture of conductor screen. |
| Partial discharge test. | Heat shock test (PVC sheaths only). | Pressure test (PVC sheaths only.) |
| High voltage a.c. test for 5 min. | Insulation shrinkage. | Loss of mass (PVC sheaths only). |
| High voltage a.c. test for 1 min on separation sheath (three core armoured cable only). | Insulation concentricity. | Volume resistivity of conductor and insulation screens |
| | Conductor screen projections/irregularities. | Mechanical tests (before and after ageing) of insulation and sheaths. |
| | Determination of voids and contaminants. | Partial discharge test after bending. |
| | Hot set test. | Impulse withstand test followed by high voltage a.c. test for 15 min. |
| | Insulation screen strip ability and adhesion. | Partial discharge test after heat cycling. |
| | | DDF ($\tan \delta$) as a function of temperature. |
| | | High voltage a.c. test for 4 h. |
| | | Compatibility test for separation sheath (if any) and over sheath. |

TEST VOLTAGE LEVELS

| Voltage Withstand Tests | | | | |
|--------------------------------|-----------------|---|-----------------------------------|-------------------------------------|
| Rated Voltage (kV) | Impulse (kV) | Type Tests | | Routine Test |
| | | High Voltage 15 min 50 Hz (after impulse test) (kV) | High Voltage 4 h 50 Hz (kV) | High Voltage 5 min 50 Hz (kV) |
| 3.8/6.6 | 60 | 12.5 | 15 | 12.5 |
| 6.35/11 | 95 | 21 | 25 | 21 |
| 12.7/22 | 150 | 42 | 50 | 42 |
| 19/33 | 200 | 63 | 75 | 63 |

| Partial Discharge Voltage Levels | | | |
|---|---------------------------------|--------------------------------|--|
| Rated Voltage (kV) | Permitted Maximum Discharge | | |
| | 20 pC at 200 percent Uo (kV) | 5 pC at 150 percent Uo (kV) | |
| 3.8/6.6 | 7.6 | 5.7 | |
| 6.35/11 | 13 | 10 | |
| 12.7/22 | 25 | 19 | |
| 19/33 | 38 | 29 | |

INSTALLATION TESTS

General

After the cable, has been installed and prior to commencing terminating or jointing, it is desirable to carry out checks to establish that the cable has not been damaged during the installation process, namely a Sheath Integrity Test and an Insulation Resistance Test of Primary Insulation. After completion of the tests, if the terminating or jointing is not being commenced straight away, the cable ends should be resealed with heat shrinkable end caps or similar to prevent the ingress of moisture.

Nexans New Zealand Recommendations for Tests After Complete Installation of TR-XLPE Medium Voltage Cables

Advice Concerning Tests After Installation

If a test is carried out after installation, please note that the test is to detect defects caused during installation. After installation, the test is applied to the cable and accessories.

High Voltage D.C. Test After Installation

The D.C. testing of the primary insulation is **NOT** recommended. There are two important reasons for **NOT** using a High Voltage DC Test.

1. The DC field in the cable and accessories applies different electric stresses (both in magnitude and in physical location) to an AC field, so much so, that it is considered to be a poor process to find faults.
2. The application of High Voltage DC leads to premature failure of aged and "wet" primary insulation. This has been proven in the Laboratory and has been proven repeatedly in the field.

Safety Requirements

As the voltages used in these tests are potentially lethal, appropriate safety measures must be employed to ensure that the safety of all people involved in the testing process is not compromised.

Cable ends to be isolated shall be disconnected from the supply and protected from contact to supply, or ground, or accidental contact. Safety measures shall include, and shall not necessarily be limited to, earthing of cable under test prior to and after test voltages are applied, erection of safety barriers with warning signs, and an open communication channel between testing personnel.

The testing guidelines outlined in this document are Nexans recommendations only, and Nexans cannot be held responsible for ensuring the safe implementation of these recommendations.

Sheath Integrity Test

A sheath integrity test (e.g., 1000 V minimum insulation resistance tester) applied between the outer-most metallic layer and earth can identify after-installation damage to the non-metallic outer sheath.

The measured value should be read after application of the voltage for 1 minute. Ideally the measured value should be corrected for temperature to a standard value at 20°C if correction factors are available. A rough guide is that the insulation resistance decreases to one half of the value for a 10°C rise in temperature. The cable temperature should be recorded along with the measured values.

Measured values of Insulation Resistance for the sheath should be greater than calculated values. Calculated values for new cable range from 1.5 MΩ/km to 4.0 MΩ/km @ 20°C for PVC sheaths and from 120 MΩ/km to 300 MΩ/km @ 20°C for PE sheaths. Values are highest for small cables and thick sheaths and lowest for large cables and thin sheaths (factory tests show that measured values are up to an order of magnitude greater than the calculated values).

Earth the screens after an Insulation Resistance Test on a sheath for at least 5 minutes before handling or performing other tests.

INSTALLATION TESTS (CONT.)

Insulation Resistance Test of Primary Insulation

DC voltages up to 5 kV, used when performing Insulation Resistance Tests on Primary Insulation, are not considered to be a "High voltage DC test".

An Insulation Resistance Test of the Primary Insulation should be carried out with an insulation resistance tester, with a minimum DC voltage of 2.5 kV for 1.9/3.3 kV cables or 5 kV for cables above 1.9/3.3 kV and up to 19/33 kV. The insulation test should be carried out in the "Guarded Mode" and the instrument should have a minimum full-scale range of 500 GΩ. Guarding should be applied at both ends and a spare core used for the connection lead to the guard at the far end. Any conductor or cable core used as a guard lead must have a resistance to ground of greater than 10 kΩ. The measured value should be read after application of the voltage for 1 minute. Ideally the measured value should be corrected for temperature to a standard value at 20°C if correction factors are available. A rough guide is that the insulation resistance decreases to one half of the value for a 10°C rise in temperature. The cable temperature should be recorded along with the measured values.

Measured values of insulation resistance for the primary insulation should be greater than calculated values. Calculated values for new cable range from 2,400 MΩ/km to 18,000 MΩ/km at 20°C. Values are highest for small conductors and higher voltages and lowest for large conductors and lower voltages (factory tests show that measured values are up to an order of magnitude greater than the calculated values).

This test should be performed prior to any high voltage tests. Short the conductors to the screens after an Insulation Resistance Test on Primary Insulation for at least 10 minutes before handling or performing other tests.

If the instrument used for the above insulation resistance testing is a "Megger," Type BM 25, or equivalent, then the two following tests should be considered.

1. A 10-minute Polarisation Index Test - this test is commonly used as a replacement for the standard insulation resistance test.
2. A 5 Minute Step Voltage Test - the test should use five equal steps up to the maximum test voltage of 2.5 kV for 1.9/3.3 kV cables or 5 kV for cables greater than 1.9/3.3 kV up to 19/33 kV. This test is becoming increasingly used on cables of 6.35/11 kV and greater.

Both the above tests can be carried out automatically with the Megger, BM 25 unit and guarding should be applied at both ends as above.

INSTALLATION TESTS (CONT.)

High Voltage A.C. Test After Installation

An A.C. voltage test at power frequency should be applied for 24 hours with the normal operating voltage of the system to the primary insulation.

Some customers have objected to a 24-hour test at only the operating voltage of the cable and would prefer a test using a higher voltage for a shorter time. This can be achieved by a Very Low Frequency (VLF) HV AC Test, and the equipment now exists for hire in New Zealand to perform this. The VLF HV AC Test is becoming recognised throughout the world as a replacement test for the old HV DC Test or the 24-hour AC test at normal operating voltage, although not many standards have details in them at this point in time. VLF Tests are carried out at a frequency in the band of 0.1 to 0.02 Hz. The VLF Test Set must be of adequate power to test the measured cable capacitance at the frequency chosen. The suggested maximum VLF test voltage for new cable is between 2.7 and 3.0 times the cable operating voltage (U_o), for a minimum of 15 minutes. Where possible, a 30-minute testing time is now recommended as international research has shown this to give a higher confidence. Refer to the test procedure of IEEE-400-2.

For existing or aged cables being recommissioned after repair or alterations, the VLF Test Voltage should be a maximum of 2.3 times the cable operating voltage (U_o), for 15 minutes.

Documentation

The values obtained in the above tests should be recorded in a cable log so that they are available for comparison purposes in the future.

CURRENT RATINGS

The continuous current ratings given in this publication have been calculated in accordance with the International Electrotechnical Commission Publication No. IEC 60287 - "Calculation of the Continuous Current Rating of Cables (100% Load factor)", based on the following environmental conditions: Ambient Air Temperature, 30°C; Ambient Soil Temperature, 15°C; Soil Thermal Resistivity, 1.2 Km/W; Depth of burial, 1.0 m; and Screens bonded both ends.

In all cases, the ratings given are the single circuit ratings corresponding to continuous loading at the maximum conductor temperature of 90°C. Where the conditions vary from those on which the ratings are based, rating factors from Tables 4.1 to 4.4 (Section 4 Medium Voltage TR-XLPE Cables) need to be applied.

Methods of Installation

The methods of installation for which the ratings are applicable are shown graphically in Figure 2.1 (Section 2 General Technical Information).

Groups of Circuits

For groups of circuits unenclosed in air, the spacings and arrangements which need to be maintained to prevent derating are given in Figure 2.2 (Section 2 General Technical Information).

Where a number of circuits are installed in close proximity in such a way that they are not thermally independent, the appropriate rating factors from Tables 4.5, 4.6, (Section 4 Medium Voltage TR-XLPE Cables) and 2.1, 2.2 (Section 2 General Technical Information) need to be applied.

Cables in Parallel

For cables operated in parallel, each parallel leg is regarded as a separate circuit for current rating purposes and the appropriate rating factors for grouping are applicable. Refer also to Figure 2.3 (Section 2 General Technical Information) for the arrangements of single core cables so as to ensure equal current sharing between parallel legs of the same phase.

Bonding of Screens

The current ratings given for single core cables assume that the copper wire screens are solidly bonded to earth at both ends. Solid bonding can result in a reduction in current ratings on larger cables due to the heating effect of circulating currents induced in the screen. This loss can be minimised, either in short runs of cable, by earthing at one end only (single point bonding) which results in a standing voltage proportional to the conductor current and the length of run being induced on the screen and in long runs of cable, by dividing the route into tri-sections and transposing or "cross bonding" the screens at every joint position in a tri-section so that the e.m.f.'s induced by the three phases cancel one another.

When these methods of bonding are employed, higher current ratings may be used, however attention must be paid to the safety aspects with respect to the induced standing voltages. This places a limitation on the length of circuit for which single point bonding can be used.

Generally, it is only considered practical to use special cross-bonding arrangements on transmission class cables (66 kV and above) as the benefits of the higher current ratings are outweighed by the costs of the extra equipment required.

Emergency Ratings

TR-XLPE insulated cables can operate under emergency conditions with a conductor temperature of 130°C for periods of up to 36 hours, not more than three times per year. In practice, however, due to the difficulty in ensuring compatibility with terminations and the high-volume expansion of TR-XLPE above 100°C, a limit of 105°C for emergency rating is specified in AS/NZS 1429.1. The 105°C emergency limit represents the following approximate percentage increase over the normal continuous ratings:

Cables in air: +12%

Cables in ground (laid direct or in ducts): +9%.

Issue: June 2019

19/33 (36) kV. Made to AS/NZS 1429.1

* Short circuit rating less than 10 kA for 1 s

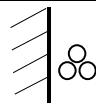

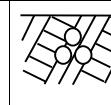

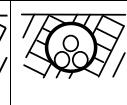

Note: Subject to confirmation, similar cables can be manufactured to other specifications.

THREE CORE AL 33 KV CABLES

Aluminium conductor
 SCXLPE conductor screen
 TR-XLPE insulation }
 SCXLPE insulation screen } Triple extruded, Dry-cure
 Copper wire screens
 PVC/HDPE sheath

Product Sheet No. 253-21 B

| Conductor Size (mm ²) | Conductor AC Resistance at 50 Hz and 90°C (Ohm/km) | Inductive Reactance at 50 Hz (Ohm/km) | Conductor to Screen Capacitance (μF/km) | Nominal PVC Duct Size (Single Way) (mm) | Current Ratings (A) | | |

Issue: June 2019

19/33 (36) kV. Made to AS/NZS 1429.1

* Short circuit rating less than 10 kA for 1 s

Note: The values in this table are for installation conditions of:

Ambient Air Temperature 30 °C

Soil Temperature 15 °C

Soil Thermal Resistivity 1.2 K.m/W

Depth of Burial 1.0 m

NOTES
